The Middle Income Trap

What separates countries that break through from those that stall?

Ziyu Ren Yuxuan Wan Shuangzi Zhang

BUS 32120

Winter 2026

Who is this for, and why does it matter?

Audience: Policymakers and development researchers in middle-income countries.

Background: Some countries hit middle-income status and then get stuck there for decades. Others power through to high income. We wanted to figure out what actually makes the difference.

Setup:

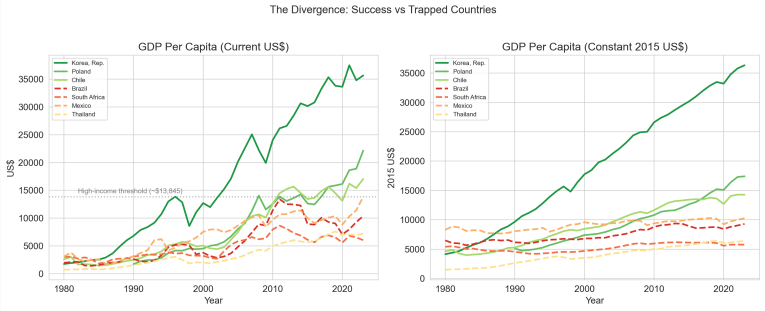
- **Success group:** South Korea, Poland, Chile — broke through
- **Trapped group:** Brazil, South Africa, Mexico, Thailand — stalled
- 15 indicators from the World Bank API, 1980–2023
- Two additional datasets: governance quality and R&D / innovation

Bottom line: what did we find?

1. The GDP gap was small in the 1980s ($1,500) but exploded to $15,000+ by the 2020s.
2. **Education** is the biggest differentiator. 78% tertiary enrollment vs 35%.
3. **R&D spending** differs by nearly 3x (1.7% vs 0.6% of GDP). Every single high-R&D observation in our data belongs to a success country.
4. **Governance** is the most consistent gap. About 1 point higher on corruption control, rule of law, and regulatory quality across all four decades.
5. Trapped countries faced far greater macro instability (Brazil's inflation hit 2,948%).
6. Our logistic regression classifies success vs trapped at **92% accuracy**.

The divergence over time

	1980s	1990s	2000s	2010s	2020s
Success	$2,501	$7,120	$12,961	$18,938	$22,834
Trapped	$1,781	$3,384	$4,835	$7,069	$8,185



Korea started at roughly the same level as Thailand. By 2023 it's at 5x.
The gap went from $700 to $15,000.

What drives the gap?

Structural differences:

- Education: 78% vs 35%
- R&D: 1.7% vs 0.6% of GDP
- Patents: 28k vs 1.6k / year
- Governance: +0.8 to +1.1 (all dimensions)

Interaction: Education works best with manufacturing.
Success: 18% have both | Trapped: 1%

Macro instability:

- Brazil hyperinflation: up to 2,948%
- Kept real events; used log scale
- IQR: 47 extreme inflation years (kept)

When we split correlations by group, education correlates much more strongly with GDP in the success group.

Feature engineering: method

We created 12 new features. Example:

```
df['growth_5yr_avg'] = (
    df.groupby('country')['gdp_growth']
    .transform(lambda x: x.rolling(5, min_periods=3).mean())
)
```

Feature	What it is
Growth 5yr avg	Rolling 5-year mean of GDP growth
Manufacturing intensity	Manufacturing $\div$ total industry (quality of industry)
Macro instability	$\lvert$inflation$\rvert$ + unemployment (higher = worse)
Edu $\times$ manufacturing	1 if both above median, 0 otherwise
Income class + OHE	GDP-based category $\rightarrow$ 4 dummy columns

Scaling: `log1p()` on inflation to compress extremes, then MinMaxScaler to 0–1.

Feature engineering: what we found

Engineered Feature	Success	Trapped	Takeaway
Macro instability index	13.9	57.2	Trapped 4x worse
High-edu + high-manuf	18%	1%	Almost exclusive to Success

Macro instability combines inflation and unemployment. Education alone isn't enough, you need it combined with strong manufacturing.

SQL analysis

We loaded the data into 4 normalized tables in SQLite and ran 12 queries covering joins, window functions (RANK, LAG), GROUP BY with ROLLUP/CUBE, and subqueries.

```
WITH rd_stats AS (
  SELECT AVG(rd_pct_gdp) AS mean_rd
  FROM innovation
  WHERE rd_pct_gdp IS NOT NULL
)
SELECT
  CASE WHEN i.rd_pct_gdp >= s.mean_rd
       THEN 'High R&D'
       ELSE 'Low R&D' END AS rd_group,
  c.group_label,
  ROUND(AVG(e.gdp_growth),2)
FROM innovation i
JOIN econ_indicators e
  ON i.country=e.country
  AND i.year=e.year
JOIN countries c ON i.country=c.country
CROSS JOIN rd_stats s
GROUP BY rd_group, c.group_label
```

Result: every single high-R&D observation belongs to a success country. Zero exceptions.

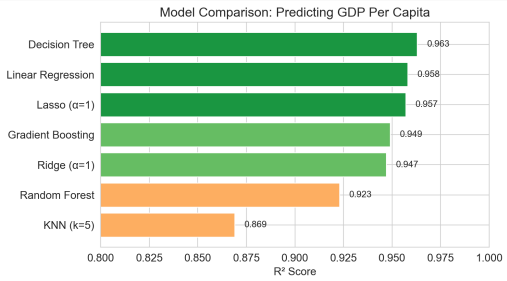
- Brazil, S. Africa, Thailand have never crossed the $13,845 high-income line
- R&D 5-year moving average shows Korea trending to 4.5%+; trapped countries flat at ∼0.5%

Models

Predicting GDP per capita

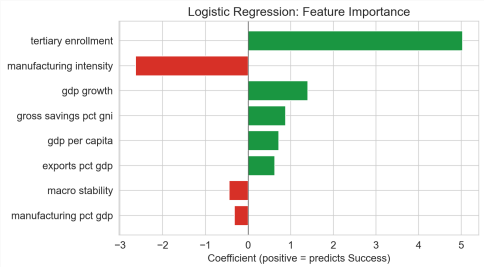
Raw features: $R^2 = 0.57 \rightarrow$ with engineered: $\mathbf{R^2 = 0.96}$

7 models compared:



Top predictor: R&D (74%), then education (17%).

Classifying success vs trapped



Accuracy: **92%** — AUC: **0.97**

Tertiary enrollment strongest positive; manufacturing intensity strongest negative as trapped countries have *higher* manufacturing but lack education and R&D.

So what should policymakers do?

Based on everything we found, three things matter most:

1. **Invest heavily in education and R&D.** These are the top predictors in every model we ran. R&D alone accounts for 74% of feature importance.
2. **Keep inflation and unemployment under control.** You can't build long-term growth on a volatile macro foundation.
3. **Build stronger institutions.** Governance quality is the most *consistent* gap — it shows up in every decade and every metric.

If we had more time: expand to 20+ countries, add UN Comtrade trade data, run panel regressions for causal inference, and look at demographics.
